

EXISTENCE OF MINIMIZERS FOR EIGENVALUES OF THE DIRICHLET-LAPLACIAN WITH A DRIFT

BARBARA BRANDOLINI¹, FRANCESCO CHIACCHIO¹, ANTOINE HENROT²,
AND CRISTINA TROMBETTI¹

ABSTRACT. This paper deals with the eigenvalue problem for the operator $L = -\Delta - x \cdot \nabla$ with Dirichlet boundary conditions. We are interested in proving the existence of a set minimizing any eigenvalue λ_k of L under a suitable measure constraint suggested by the structure of the operator. More precisely we prove that for any $c > 0$ and $k \in \mathbb{N}$ the following minimization problem

$$\min \left\{ \lambda_k(\Omega) : \Omega \text{ quasi-open set, } \int_{\Omega} e^{|x|^2/2} dx \leq c \right\}$$

has a solution.

1. INTRODUCTION

In this paper we are interested in the following eigenvalue problem for the Dirichlet-Laplacian with a drift term

$$(1.1) \quad \begin{cases} -\Delta u - x \cdot \nabla u = \lambda u & \text{in } \Omega \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

or equivalently in the weighted eigenvalue problem

$$(1.2) \quad \begin{cases} -\operatorname{div} \left(e^{|x|^2/2} \nabla u \right) = \lambda e^{|x|^2/2} u & \text{in } \Omega \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is an open subset of \mathbb{R}^N ($N \geq 2$). Let us denote

$$dm_N = \prod_{i=1}^N e^{\frac{x_i^2}{2}} dx_i, \quad x = (x_1, \dots, x_N) \in \mathbb{R}^N,$$

and let $H_0^1(\Omega; m_N)$ be the closure of $C_0^\infty(\Omega)$ with respect to the norm

$$\|u\|_{H_0^1(\Omega; m_N)} = \left(\|u\|_{L^2(\Omega; m_N)}^2 + \|\nabla u\|_{L^2(\Omega; m_N)}^2 \right)^{1/2}.$$

The operator $\mathcal{R} : f \in L^2(\Omega; m_N) \rightarrow \varphi \in H_0^1(\Omega; m_N)$, where φ is the unique solution to

$$(1.3) \quad \begin{cases} -\operatorname{div} \left(e^{|x|^2/2} \nabla \varphi \right) = f e^{|x|^2/2} & \text{in } \Omega \\ \varphi = 0 & \text{on } \partial\Omega, \end{cases}$$

is compact, self-adjoint and nonnegative (see Section 2); then the spectrum of \mathcal{R} is purely discrete, it consists only of eigenvalues which can be ordered (according to their multiplicity):

$$0 < \lambda_1(\Omega) \leq \lambda_2(\Omega) \leq \dots \leq \lambda_k(\Omega) \leq \dots$$

Our main result is the following

Theorem 1.1. *For any $c > 0$ the minimum*

$$(1.4) \quad \min\{\lambda_k(\Omega) : \Omega \subset \mathbb{R}^N, \Omega \text{ quasi-open set}, m_N(\Omega) \leq c\}$$

is achieved.

For the definition of quasi-open sets we remind the reader to Remark 3.1 and the references mentioned therein. Let us briefly discuss how our result is inserted in the literature. In the case of Laplace operator, the analogous minimization problem with Lebesgue measure constraint has been faced for the first time by Buttazzo and Dal Maso in [11]. Their key assumption is that Ω varies in the class of sets contained in the same box D . Replacing D with \mathbb{R}^N is far from being simple due to the lack of compactness for generic sequences of sets. Very recently, this problem has been overcome independently by Mazzoleni and Pratelli in [21] and Bucur in [10] with different techniques. In our case, the set Ω is allowed to vary in the whole \mathbb{R}^N since the structure of the operator and the m_N measure constraint allow us to earn the compact embedding of the weighted Sobolev space $H_0^1(\Omega; m_N)$ into the weighted Lebesgue space $L^2(\Omega; m_N)$ (see Theorem 2.2 below).

On the other hand problem (1.1) can be viewed as a prototype of a more general class of eigenvalue problems. For instance in [14] (see also the references therein), among other things, the problem of minimizing the first eigenvalue of

$$\begin{cases} -\operatorname{div} (A(x) \nabla u) + v \cdot \nabla u + Vu = \lambda u & \text{in } \Omega \\ u = 0 & \text{on } \partial\Omega \end{cases}$$

is addressed under various constraints on A, v, V, Ω by using a new notion of rearrangement. To our knowledge the existence of a domain minimizing a generic eigenvalue of problem (1.1) has not been established yet. In this paper we solve this question under the natural “weighted volume constraint”.

Using an appropriate notion of rearrangement, see for instance [9, 26], a Faber-Krahn type inequality can be proved: the ball centered at the origin is the optimal domain for the first eigenvalue (i.e. the case $k = 1$). Now all the other cases are open. In the classical situation (the Dirichlet-Laplacian with a constraint on the Lebesgue measure) only two cases are solved: for $k = 1$, the minimizer is any ball (Faber-Krahn inequality), while for $k = 2$, it is the union of two identical balls (Krahn-Szögo inequality), see [15] for more details. In our situation, even the case $k = 2$ is not clear because of the measure m_N . In [3] we study this problem and prove, among other things, that the optimal domain is not composed of two identical balls.

The proof of Theorem 1.1 can be summarized as follows. We consider a minimizing sequence of quasi-open sets Ω_n and we construct the sequence of functions $w_n \in H_0^1(\Omega_n; m_N)$ solving problem (1.3) in Ω_n with $f \equiv 1$. We prove that w_n strongly converge to a function w in

$L^2(\mathbb{R}^N; m_N)$ and we define $\hat{\Omega} = \{w > 0\}$. We prove that the eigenfunctions u_j^n corresponding to $\lambda_j(\Omega_n)$ weakly converge to $u_j \in H_0^1(\hat{\Omega}; m_N)$. We conclude that $\lambda_j(\hat{\Omega})$ is the minimum of problem (1.4). The paper is organized as follows. In Section 2 we recall the compact embedding of $H_0^1(\mathbb{R}^N; m_N)$ into $L^2(\mathbb{R}^N; m_N)$ and we provide an Hardy type inequality which in turn gives an improved embedding theorem. In Section 3 we prove a sharp reverse Hölder inequality for eigenfunctions that will be used to ensure the suitable convergence of u_j^n . Note that these results may have an interest by their own. Finally Section 4 contains the proof of Theorem 1.1.

2. SOME PROPERTIES OF WEIGHTED SOBOLEV SPACES

2.1. Weighted isoperimetric inequalities and rearrangements. We start this section by recalling the isoperimetric inequality with respect to the measure m_N . Let $\Omega \subset \mathbb{R}^N$ be a Lebesgue measurable set, we define the weighted perimeter of Ω with respect to m_N by

$$P_{m_N}(\Omega) = \sup \left\{ \int_{\Omega} \operatorname{div} \left(\mathbf{k}(x) e^{|x|^2/2} \right) dx : \mathbf{k} \in C_0^1(\mathbb{R}^N, \mathbb{R}^N), |\mathbf{k}| \leq 1 \right\}.$$

For any smooth set $\Omega \subset \mathbb{R}^N$ it reduces to

$$P_{m_N}(\Omega) = \int_{\partial\Omega} e^{|x|^2/2} d\mathcal{H}^{N-1}.$$

In [9] (see also [7, 8]) the authors prove the following result.

Theorem 2.1. *For any set $\Omega \subset \mathbb{R}^N$ with finite m_N -measure,*

$$(2.1) \quad P_{m_N}(\Omega) \geq P_{m_N}(\Omega^\star),$$

where Ω^\star is the ball centered at the origin, having the same m_N -measure as Ω . Equality sign holds in (2.1) if and only if $\Omega = \Omega^\star$.

As well-known, (2.1) turns out to be the key ingredient for a Faber-Krahn type inequality to hold (see Proposition 2.5). To this aim we give the notion of rearrangement with respect to the measure m_N .

Let ϕ be a measurable real function defined in Ω . The distribution function of ϕ with respect to the m_N -measure is defined by

$$\mu(t) = m_N(\{x \in \Omega : |\phi(x)| > t\}), \quad t \geq 0,$$

while the decreasing rearrangement of ϕ with respect to the m_N -measure is the function

$$\phi^*(s) = \sup \{t \geq 0 : \mu(t) > s\}, \quad s \in (0, m_N(\Omega)).$$

It is easy to see that ϕ^* is a nonincreasing, right-continuous function defined in $(0, m_N(\Omega))$, equidistributed with ϕ , that means ϕ and ϕ^* have corresponding superlevel sets with the same m_N -measure. This feature implies that

$$\|\phi\|_{L^p(\Omega; m_N)} = \|\phi^*\|_{L^p(0, m_N(\Omega))}, \quad \forall p \geq 1.$$

Now we set

$$h(r) = N\omega_N e^{r^2/2} r^{N-1}, \quad H(r) = \int_0^r h(t) dt,$$

where ω_N is the Lebesgue measure of the unit ball in \mathbb{R}^N . Then

$$P_{m_N}(\Omega^\star) = h(H^{-1}(m_N(\Omega)))$$

and (2.1) reads as

$$P_{m_N}(\Omega) \geq h \left(H^{-1}(m_N(\Omega)) \right).$$

We finally define ϕ^\star , the m_N -symmetrization of ϕ , as follows

$$\phi^\star(x) = \phi^*(H(|x|)), \quad x \in \Omega^\star.$$

ϕ^\star is the only spherically symmetric function, nonincreasing along the radii, whose level sets are balls centered at the origin, with the same m_N measure as the corresponding level sets of $|\phi|$. This definition immediately implies

$$\|\phi\|_{L^p(\Omega; m_N)} = \|\phi^\star\|_{L^p(\Omega^\star; m_N)}, \quad \forall p \geq 1.$$

The following inequalities hold true.

Proposition 2.1 (Hardy-Littlewood inequality). *Let $\phi, \psi \in L^2(\Omega; m_N)$; then*

$$(2.2) \quad \int_{\Omega} |\phi\psi| dm_N \leq \int_0^{m_N(\Omega)} \phi^*(s)\psi^*(s)ds = \int_{\Omega^\star} \phi^\star\psi^\star dm_N.$$

Proposition 2.2 (Pólya-Szegő principle). *If $\phi \in H^1(\mathbb{R}^N; m_N)$, $\phi \geq 0$, then $\phi^\star \in H^1(\mathbb{R}^N; m_N)$ and*

$$(2.3) \quad \int_{\mathbb{R}^N} |\nabla \phi|^2 dm_N \geq \int_{\mathbb{R}^N} |\nabla \phi^\star|^2 dm_N.$$

For an exhaustive treatment on rearrangements see, for instance, [18, 28, 15, 19, 2].

2.2. Weighted Sobolev spaces and embedding theorems. In order to prove the existence of the optimal set in (1.4) let us introduce the natural Sobolev spaces associated with problem (1.2). Let Ω be an arbitrary open subset of \mathbb{R}^N ; let us consider the weighted Lebesgue space

$$L^q(\Omega; m_N) = \left\{ u : \Omega \rightarrow \mathbb{R} : \int_{\Omega} |u|^q dm_N < +\infty \right\}, \quad q \geq 1,$$

endowed with the norm

$$\|u\|_{L^q(\Omega; m_N)} = \left(\int_{\Omega} |u|^q dm_N \right)^{1/q},$$

and let $H_0^1(\Omega; m_N)$ be the closure of $C_0^\infty(\Omega)$ with respect to the norm

$$\|u\|_{H_0^1(\Omega; m_N)} = \left(\|u\|_{L^2(\Omega; m_N)}^2 + \|\nabla u\|_{L^2(\Omega; m_N)}^2 \right)^{1/2}.$$

We initially observe that, for any $\Omega \subseteq \mathbb{R}^N$, if $u \in H_0^1(\Omega; m_N)$ and we define $v = ue^{|x|^2/4}$, we get the following equivalence.

Proposition 2.3.

$$u \in H_0^1(\Omega; m_N) \iff v \in H_0^1(\Omega), \quad |x|v \in L^2(\Omega).$$

The following Poincaré inequality is well-known (see for instance [13]).

Proposition 2.4. *For every $u \in H^1(\mathbb{R}^N; m_N)$ it holds*

$$(2.4) \quad \int_{\mathbb{R}^N} |\nabla u|^2 dm_N \geq N \int_{\mathbb{R}^N} u^2 dm_N.$$

The following theorem provides the compact embedding of $H^1(\mathbb{R}^N; m_N)$ into $L^2(\mathbb{R}^N; m_N)$. Nevertheless this result can be found in [13], for the reader's convenience we recall it here.

Theorem 2.2. *The weighted Sobolev space $H^1(\mathbb{R}^N; m_N)$ is compactly embedded into the weighted Lebesgue space $L^2(\mathbb{R}^N; m_N)$.*

Proof. Let $u_n \in H^1(\mathbb{R}^N; m_N)$ be such that

$$(2.5) \quad \int_{\mathbb{R}^N} |\nabla u_n|^2 dm_N \leq C, \quad n \in \mathbb{N},$$

and let $v_n = u_n e^{|x|^2/4}$. Integrating by parts we get

$$\int_{\mathbb{R}^N} |\nabla v_n|^2 dx + \frac{1}{4} \int_{\mathbb{R}^N} |x|^2 v_n^2 dx \leq \int_{\mathbb{R}^N} |\nabla u_n|^2 dm_N$$

and (2.5) immediately gives

$$(2.6) \quad \int_{\mathbb{R}^N} |\nabla v_n|^2 dx \leq C$$

$$(2.7) \quad \int_{\mathbb{R}^N} |x|^2 v_n^2 dx \leq C.$$

In order to prove the compactness of the sequence $\{v_n\}$ in $L^2(\mathbb{R}^N)$ it is enough to show that for any $\varepsilon > 0$ there exist a constant $\delta > 0$ and a set $D \subset \mathbb{R}^N$ such that

$$(2.8) \quad \int_{\mathbb{R}^N} |v_n(x + \tau) - v_n(x)|^2 dx < \varepsilon^2, \quad \forall n \in \mathbb{N}, \forall \tau \in \mathbb{R}^N : |\tau| < \delta,$$

$$(2.9) \quad \int_{\mathbb{R}^N \setminus \bar{D}} v_n^2 dx < \varepsilon^2, \quad \forall n \in \mathbb{N}.$$

(2.8) is an immediate consequence of (2.6). In order to prove (2.9) let us consider a ball B_R centered at the origin, with radius R ; by (2.7) we get

$$\int_{\mathbb{R}^N \setminus B_R} v_n^2 dx \leq \frac{C}{R^2}$$

and choosing R in such a way that $\frac{C}{R^2} < \varepsilon^2$ we have (2.9). Then, up to a subsequence, v_n strongly converge to a function v in $L^2(\mathbb{R}^N)$. Let $u = v e^{-|x|^2/4}$. Clearly $u \in L^2(\mathbb{R}^N; m_N)$ and u_n strongly converge to u in $L^2(\mathbb{R}^N; m_N)$. □

By the above result, as mentioned in the Introduction, the operator $\mathcal{R} : f \in L^2(\Omega; m_N) \rightarrow \varphi \in H_0^1(\Omega; m_N)$, where φ is the unique solution to

$$\begin{cases} -\operatorname{div} \left(e^{|x|^2/2} \nabla \varphi \right) = f e^{|x|^2/2} & \text{in } \Omega \\ \varphi = 0 & \text{on } \partial\Omega, \end{cases}$$

is compact; it is clearly self-adjoint and nonnegative, then the spectrum of \mathcal{R} consists only of eigenvalues which can be ordered (according to their multiplicity):

$$0 < \lambda_1(\Omega) \leq \lambda_2(\Omega) \leq \dots \leq \lambda_k(\Omega) \leq \dots$$

Moreover, for every $k \in \mathbb{N}$ and every $\lambda_k(\Omega)$ the following min-max formula holds

$$(2.10) \quad \lambda_k(\Omega) = \min_{\substack{V \text{ subspace of dim-} \\ \text{ension } k \text{ of } H_0^1(\Omega; m_N)}} \max_{v \in V} \frac{\int_{\Omega} |\nabla v|^2 dm_N}{\int_{\Omega} v^2 dm_N}.$$

Problem (1.4) is completely solved when $k = 1$. Indeed, using Pólya-Szegő inequality (2.3) and the variational characterization of the first eigenvalue, arguing as for the Dirichlet-Laplacian, the following result can be easily proven.

Proposition 2.5. *Let Ω be an open subset of \mathbb{R}^N with finite m_N measure. Then*

$$\lambda_1(\Omega) \geq \lambda_1(\Omega^\star).$$

2.3. An Hardy type inequality and consequences. In [13] the authors, among other things, prove that, if $N \geq 3$ and $2^* = \frac{2N}{N-2}$, then

$$\begin{aligned} S &:= \inf \left\{ \frac{\int_{\mathbb{R}^N} |\nabla \varphi|^2 dx}{\left(\int_{\mathbb{R}^N} |\varphi|^{2^*} dx\right)^{2/2^*}} : \varphi \in H^1(\mathbb{R}^N) \setminus \{0\} \right\} \\ &= \inf \left\{ \frac{\int_{\mathbb{R}^N} |\nabla \varphi|^2 dm_N}{\left(\int_{\mathbb{R}^N} |\varphi|^{2^*} dm_N\right)^{2/2^*}} : \varphi \in H^1(\mathbb{R}^N; m_N) \setminus \{0\} \right\} \end{aligned}$$

and, as a corollary, they get that for every $u \in H^1(\mathbb{R}^N; m_N)$

$$\int_{\mathbb{R}^N} |\nabla u|^2 dm_N \geq S \left(\int_{\mathbb{R}^N} u^{2^*} dm_N \right)^{2/2^*} + \frac{N}{2} \int_{\mathbb{R}^N} u^2 dm_N.$$

Moreover, by interpolation between $L^2(\mathbb{R}^N; m_N)$ and $L^{2^*}(\mathbb{R}^N; m_N)$ they obtain that for any $2 \leq q \leq 2^*$ there exists a positive constant C such that if $\frac{1}{q} = \frac{a}{2} + \frac{1-a}{2^*}$ and $u \in H^1(\mathbb{R}^N; m_N)$ then

$$\|u\|_{L^q(\mathbb{R}^N; m_N)} \leq C \|u\|_{L^2(\mathbb{R}^N; m_N)}^a \|\nabla u\|_{L^2(\mathbb{R}^N; m_N)}^{1-a}.$$

We go further by proving a Hardy type inequality with respect to the measure m_N (see for example [29, 4]). This inequality, as in the classical case, will imply that, if $N \geq 3$, $H^1(\mathbb{R}^N; m_N)$ is continuously embedded into the weighted Lorentz space $L^{2^*, 2}(\mathbb{R}^N; m_N)$ and a fortiori in $L^{2^*}(\mathbb{R}^N; m_N)$. When $N = 2$ we gain that $H^1(\mathbb{R}^2; m_2)$ is continuously embedded into a suitable Orlicz space.

Let

$$\rho_N(r) = \frac{r^{1-N} e^{-r^2/2}}{\int_r^{+\infty} t^{1-N} e^{-t^2/2} dt}, \quad r \geq 0.$$

Clearly

$$\lim_{r \rightarrow 0^+} \rho_N(r) = +\infty, \quad \lim_{r \rightarrow +\infty} \rho_N(r) = +\infty,$$

and

$$\lim_{r \rightarrow 0^+} r \rho_N(r) = N - 2 \quad \text{if } N \geq 3, \quad \lim_{r \rightarrow 0^+} r \log \left(\frac{1}{r} \right) \rho_N(r) = 1 \quad \text{if } N = 2.$$

Moreover ρ_N solves the following differential equation

$$(2.11) \quad \rho'_N(r) + \frac{N-1}{r} \rho_N(r) + r \rho_N(r) = \rho_N^2(r);$$

by differentiating (2.11) we immediately get that ρ_N cannot have positive maxima. Thus it has a unique minimum point $T > 0$ where $\rho_N(T) > 0$.

Lemma 2.1. *For every $\psi \in C_0^\infty(0, +\infty)$ it holds*

$$\int_0^{+\infty} (\psi'(r))^2 r^{N-1} e^{r^2/2} dr \geq \frac{1}{4} \int_0^{+\infty} \psi(r)^2 \rho_N(r)^2 r^{N-1} e^{r^2/2} dr.$$

Moreover $\frac{1}{4}$ is sharp.

Proof. Since $(\psi'(r) + \frac{1}{2}\rho_N(r)\psi(r))^2 \geq 0$, integrating by parts we get

$$\int_0^{+\infty} (\psi'(r))^2 r^{N-1} e^{r^2/2} dr \geq \frac{1}{2} \int_0^{+\infty} \psi(r)^2 r^{N-1} e^{r^2/2} \left[\rho'_N(r) + \frac{N-1}{r} \rho_N(r) + r \rho_N(r) - \frac{1}{2} \rho_N(r)^2 \right] dr$$

and from (2.11) we immediately deduce the claim.

In order to prove that the constant $\frac{1}{4}$ is sharp it suffices to consider the following sequence of functions

$$\psi_k(r) = \begin{cases} \left(\int_{1/k}^{+\infty} t^{1-N} e^{-t^2/2} dt \right)^{1/2} & r \in (0, \frac{1}{k}) \\ \left(\int_r^{+\infty} t^{1-N} e^{-t^2/2} dt \right)^{1/2} & r \in (\frac{1}{k}, +\infty) \end{cases}$$

and verify that

$$\lim_{k \rightarrow +\infty} \frac{\int_0^{+\infty} (\psi'_k(r))^2 r^{N-1} e^{r^2/2} dr}{\int_0^{+\infty} \psi_k(r)^2 \rho_N(r)^2 r^{N-1} e^{r^2/2} dr} = \frac{1}{4}.$$

□

The following Hardy inequality holds true.

Theorem 2.3. *For every $u \in H^1(\mathbb{R}^N; m_N)$ it holds*

$$(2.12) \quad \int_{\mathbb{R}^N} |\nabla u|^2 dm_N \geq \frac{1}{4} \int_{\mathbb{R}^N} u^2 \rho_{N,T}(|x|)^2 dm_N,$$

where

$$\rho_{N,T}(r) = \begin{cases} \rho_N(r) & 0 < r < T \\ \rho_N(T) & r \geq T. \end{cases}$$

Moreover $\frac{1}{4}$ is sharp.

Proof of Theorem 2.3. Let $u \in H^1(\mathbb{R}^N; m_N)$. Taking into account (2.3) and (2.2) it is enough to prove the claim when $u = u^\star$. In this case

$$\int_{\mathbb{R}^N} |\nabla u|^2 dm_N = N \omega_N \int_0^{+\infty} (u^*(H(r)))'^2 r^{N-1} e^{r^2/2} dr$$

and

$$\int_{\mathbb{R}^N} u^2 \rho_{N,T}^2 dm_N = N \omega_N \int_0^{+\infty} u^*(H(r))^2 \rho_{N,T}(r)^2 r^{N-1} e^{r^2/2} dr.$$

We get (2.12) by applying Lemma 2.1 and $0 < \rho_{N,T}(r) \leq \rho_N(r)$, $r > 0$. □

Let $N \geq 3$ and $u \in H^1(\mathbb{R}^N; m_N)$. Pólya-Szëgo principle (2.3) together with Hardy inequality (2.12) yield

$$\begin{aligned} \int_{\mathbb{R}^N} |\nabla u|^2 dm_N &\geq \int_{\mathbb{R}^N} |\nabla u^\star|^2 dm_N \geq \frac{1}{4} \int_{\mathbb{R}^N} (u^\star)^2 \rho_{N,T}(|x|)^2 dm_N \\ &= \frac{1}{4} \int_0^{+\infty} u^*(t)^2 \rho_{N,T}(H^{-1}(t))^2 dt. \end{aligned}$$

Observing that $2/2^* - 1 = -2/N$ and

$$\lim_{t \rightarrow 0^+} \frac{H^{-1}(t)}{t^{1/N}} = \omega_N^{-1/N}$$

we get

$$\int_{\mathbb{R}^N} |\nabla u|^2 dm_N \geq C \int_0^{+\infty} u^*(t)^2 t^{2/2^*-1} dt,$$

that is $H^1(\mathbb{R}^N; m_N)$ is continuously embedded in the Lorentz space $L^{2^*,2}(\mathbb{R}^N; m_N)$ (see for instance [17, 20] for the definition). On the other hand, when $N = 2$ we obtain

$$\int_{\mathbb{R}^N} |\nabla u|^2 dm_N \geq C \int_0^{+\infty} \frac{u^*(t)^2}{t \max\{1, \log(1/t)\}^2} dt.$$

By [23] (see Theorem 4.2 and Theorem 8.8) we deduce that there exist $\gamma_0, \gamma_\infty > 0$ such that

$$\int_{0^+} \exp(\gamma_0 u^*(t)^2) dt < +\infty, \quad \int_0^{+\infty} \exp(-\gamma_\infty u^*(t)^2) dt < +\infty.$$

3. A REVERSE HÖLDER INEQUALITY

Let u_j be an eigenfunction corresponding to the eigenvalue λ_j of the problem under consideration, i.e.

$$(3.1) \quad \begin{cases} -\operatorname{div}(e^{|x|^2/2} \nabla u_j) = \lambda_j(\Omega) e^{|x|^2/2} u_j & \text{in } \Omega \\ u_j = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is an open subset of \mathbb{R}^N ($N \geq 2$) with finite m_N -measure. The main result of this section is a sharp reverse Hölder inequality for u_j . In the case of the Dirichlet-Laplacian, this kind of estimates has been proved in [24, 12].

The first step in our arguments consists into introducing a ball $B_{\tilde{r}}$ such that $\lambda_j(\Omega) = \lambda_j(B_{\tilde{r}})$. Since the explicit value of $\lambda_j(B_{\tilde{r}})$ is not known, we estimate it from above and below in terms of \tilde{r} . To this aim observe that, if u_j is a solution to (3.1), the function $v_j = u_j e^{|x|^2/4}$ satisfies the following Dirichlet problem for the harmonic oscillator

$$(3.2) \quad \begin{cases} -\Delta v_j + \frac{1}{4}|x|^2 v_j = \nu_j(\Omega) v_j & \text{in } \Omega \\ v_j = 0 & \text{on } \partial\Omega \end{cases}$$

with $\nu_j(\Omega) = \lambda_j(\Omega) - \frac{N}{2}$.

When $\Omega = \mathbb{R}^N$ the spectrum and the eigenfunctions of (3.2) are explicitly known (see for instance [13]). In particular the spectrum is given by $\{\nu_j(\mathbb{R}^N) = N + j - 1 : j = 1, 2, \dots\}$. When $j = 1$, $\nu_1(\mathbb{R}^N) = N$ is simple and a corresponding eigenfunction is $e^{-|x|^2/2}$.

When $\Omega \subset \mathbb{R}^N$, since the eigenvalues of (3.2) are decreasing with respect to inclusion of sets, we get

$$(3.3) \quad \nu_j(\Omega) \geq \nu_1(\mathbb{R}^N) \iff \lambda_j(\Omega) \geq \frac{3}{2}N.$$

Moreover, using v_j as test function in (3.2) we get

$$\lambda_j(\Omega) - \frac{N}{2} \geq \frac{\int_{\Omega} |\nabla v_j|^2 dx}{\int_{\Omega} v_j^2 dx} \geq \min \left\{ \frac{\int_{\Omega} |\nabla \varphi|^2 dx}{\int_{\Omega} \varphi^2 dx} : \varphi \in H_0^1(\Omega) \setminus \{0\} \right\} = \lambda_1^{-\Delta}(\Omega)$$

where $\lambda_1^{-\Delta}(\Omega)$ is the first eigenvalue of the Dirichlet-Laplacian in Ω . Whenever Ω has finite m_N -measure, by the well-known Faber-Krahn inequality, if B_R is a ball with the same Lebesgue measure as Ω , it holds

$$\lambda_1^{-\Delta}(\Omega) \geq \lambda_1^{-\Delta}(B_R) = \frac{j_{N/2-1,1}^2}{R^2}$$

being $j_{N/2-1,1}$ the first zero of the Bessel function of the first kind of order $\frac{N}{2} - 1$. Thus

$$(3.4) \quad \lambda_j(\Omega) \geq \frac{N}{2} + \frac{j_{N/2-1,1}^2}{R^2}.$$

Incidentally we note that

$$\lambda_1(\Omega) \leq \frac{N}{2} + \lambda_1^{-\Delta}(\Omega) + \frac{R_{\Omega}^2}{4},$$

where R_{Ω} is the radius of the smallest ball centered at the origin and containing Ω .

Now, let us come back to problem (3.1). From now on we will suppose that Ω has finite m_N -measure. By integrating the equation in (3.1) on the superlevel sets of u_j , using isoperimetric inequality (2.1), co-area formula and Hölder inequality, according to a technique introduced by Talenti in [27], in [9] it is proved that

$$\begin{cases} -U_j''(s) \leq \lambda_j(\Omega) I^{-2}(s) U_j(s) & \text{in } (0, m_N(\Omega)) \\ U_j(0) = U_j'(m_N(\Omega)) = 0, \end{cases}$$

where

$$U_j(s) = \int_0^s u_j^*(t) dt$$

and

$$I(s) = \inf \{ P_{m_N}(E) : E \text{ smooth, } m_N(E) = s \} = h(H^{-1}(s))$$

is the isoperimetric function associated to the measure m_N .

For any fixed $L > 0$ we consider the following Sturm-Liouville problem

$$(3.5) \quad \begin{cases} -\varphi''(s) = \sigma I^{-2}(s) \varphi(s) & \text{in } (0, L) \\ \varphi(0) = \varphi'(L) = 0. \end{cases}$$

Since

$$\lim_{s \rightarrow 0^+} \frac{I(s)}{s^{1-\frac{1}{N}}} = N \omega_N^{\frac{1}{N}} > 0,$$

the Sobolev space $\{\varphi \in H^1(0, L) : \varphi(0) = 0\}$ is compactly embedded into the weighted Lebesgue space

$$L^2((0, L); I^{-2}) = \left\{ \varphi : (0, L) \rightarrow \mathbb{R} : \|\varphi\|_{L^2((0, L); I^{-2})}^2 \equiv \int_0^L (\varphi(t))^2 I^{-2}(t) dt < +\infty \right\}$$

(see [22, 6]). Therefore spectral theory on selfadjoint compact operators ensures that the first eigenvalue $\sigma_1(0, L)$ of (3.5) is simple and it can be found as the minimum of the Rayleigh quotient

$$\min_{\substack{\varphi \in H^1(0, L), \\ \varphi(0) = 0, \varphi \not\equiv 0}} \frac{\int_0^L (\varphi'(t))^2 dt}{\int_0^L (\varphi(t))^2 I^{-2}(t) dt}.$$

Now we claim that there exists a value of L , say \tilde{L} , such that

$$\sigma_1(0, \tilde{L}) = \lambda_j(\Omega).$$

To this aim consider the problem

$$(3.6) \quad \begin{cases} -\operatorname{div} \left(e^{|x|^2/2} \nabla z \right) = \lambda e^{|x|^2/2} z & \text{in } B_r \\ z = 0 & \text{on } \partial B_r, \end{cases}$$

where B_r denotes the ball centered at the origin having radius r . By Theorem 2.2 the first eigenvalue $\lambda_1(B_r)$ of (3.6) fulfills

$$\lambda_1(B_r) = \min \left\{ \frac{\int_{B_r} |\nabla \psi|^2 dm_N}{\int_{B_r} \psi^2 dm_N} : \psi \in H_0^1(B_r; m_N) \setminus \{0\} \right\}.$$

By (2.3) we know that such a minimum is achieved on a function z such that

$$z(x) = z^\star(x).$$

At this point it is easy to verify that $\lambda_1(B_r)$ is a continuous and strictly decreasing function with respect to r . Moreover an easy consequence of (3.3), (3.4) is

$$\lim_{r \rightarrow 0^+} \lambda_1(B_r) = +\infty \quad \text{and} \quad \lim_{r \rightarrow +\infty} \lambda_1(B_r) = \frac{3}{2}N.$$

Therefore there exists a unique value of r , say \tilde{r} , such that

$$\lambda_1(B_{\tilde{r}}) = \lambda_j(\Omega).$$

Let us denote with \tilde{z} an eigenfunction corresponding to $\lambda_1(B_{\tilde{r}})$; it is easy to verify that the function

$$Z(s) = \int_0^s \tilde{z}^*(t) dt$$

satisfies (3.5) with $\sigma_1(0, \tilde{L}) = \lambda_1(B_{\tilde{r}}) = \lambda_j(\Omega)$. Note that if $\tilde{L} = m_N(\Omega)$ the results we are going to state become trivial since in this case U_j and Z are proportional. So from now on we will assume that $\tilde{L} < m_N(\Omega)$ and we will define the function $Z(s)$ on the whole interval $(0, m_N(\Omega))$ by setting its value constantly equal to $Z(\tilde{L})$ on $(\tilde{L}, m_N(\Omega))$.

The following comparison result holds true. We omit the proof, since it can be obtained following, for instance, the lines of [1, 5].

Proposition 3.1. *If u_j and \tilde{z} are defined as above and*

$$\int_0^{m_N(\Omega)} (u_j^*(t))^q dt = \int_0^{\tilde{L}} (\tilde{z}^*(t))^q dt \quad \text{with } q > 0$$

then

$$\int_0^s (u_j^*(t))^q dt \leq \int_0^s (\tilde{z}^*(t))^q dt, \quad s \in (0, \tilde{L}).$$

The above result immediately implies the following reverse Hölder inequality.

Theorem 3.1. *For any $0 < r < q \leq \infty$, u_j satisfies the inequality*

$$(3.7) \quad \left(\int_{\Omega} |u_j|^q dm_N \right)^{1/q} \leq C(N, r, q, \lambda_j(\Omega)) \left(\int_{\Omega} |u_j|^r dm_N \right)^{1/r},$$

where

$$C(N, r, q, \lambda_j(\Omega)) = \frac{\left(\int_0^{\tilde{L}} \tilde{z}^*(t)^q dt \right)^{1/q}}{\left(\int_0^{\tilde{L}} \tilde{z}^*(t)^r dt \right)^{1/r}}$$

with \tilde{z} defined as above.

Remark 3.1. The previous inequality is stated for any open set Ω with finite m_N -measure. Actually, it also holds for any quasi-open set Ω with finite m_N -measure. To see that, we can use the definition of a quasi-open set (see for example [16, chapter 3]) to approach Ω by a sequence of open sets Ω_ε such that $\Omega \subset \Omega_\varepsilon$ and the capacity of the difference $\Omega_\varepsilon \setminus \Omega$ is less than ε . Then Ω_ε γ -converges to Ω and therefore the eigenfunctions and the eigenvalues of Ω_ε converge to the corresponding eigenfunctions and eigenvalues of Ω allowing to pass to the limit in (3.7).

4. PROOF OF THEOREM 1.1

Let Ω_n be a minimizing sequence, and let w_n be the solution to

$$(4.1) \quad \begin{cases} -\Delta w_n - x \cdot \nabla w_n = 1 & \text{in } \Omega_n \\ w_n = 0 & \text{on } \partial\Omega_n. \end{cases}$$

Choosing w_n as test function in (4.1) and using Poincaré inequality (2.4) we get that the sequence w_n is bounded in $H^1(\mathbb{R}^N; m_N)$. The compact embedding of $H^1(\mathbb{R}^N; m_N)$ in $L^2(\mathbb{R}^N; m_N)$ ensures the existence of a subsequence, still denoted by w_n , and the existence of a function $w \in H^1(\mathbb{R}^N; m_N)$ such that

$$\begin{aligned} w_n &\rightharpoonup w && \text{in } H^1(\mathbb{R}^N; m_N) \\ w_n &\rightarrow w && \text{in } L^2(\mathbb{R}^N; m_N) \\ w_n &\rightarrow w && \text{a.e. in } \Omega. \end{aligned}$$

Let us consider the quasi-open set

$$(4.2) \quad \hat{\Omega} = \{x \in \mathbb{R}^N : w(x) > 0\}.$$

Since w_n converges a.e. to w , we have for a.e. $x \in \mathbb{R}^N$

$$\chi_{\hat{\Omega}}(x) \leq \liminf_n \chi_{\Omega_n}(x);$$

therefore Fatou's Lemma gives

$$m_N(\hat{\Omega}) = \int_{\mathbb{R}^N} \chi_{\hat{\Omega}}(x) dm_N \leq \liminf_n \int_{\mathbb{R}^N} \chi_{\Omega_n}(x) dm_N \leq c.$$

We want to prove that

$$\lambda_k(\hat{\Omega}) = \min\{\lambda_k(\Omega) : m_N(\Omega) \leq c\}.$$

Let u_n^j be an eigenfunction corresponding to $\lambda_j(\Omega_n)$, $1 \leq j \leq k$, normalized as follows

$$(4.3) \quad \int_{\Omega_n} (u_n^j)^2 dm_N = 1.$$

By Theorem 2.2 there exist k function u^j such that

$$\begin{aligned} u_n^j &\rightharpoonup u^j && \text{in } H^1(\mathbb{R}^N; m_N) \\ u_n^j &\rightarrow u^j && \text{in } L^2(\mathbb{R}^N; m_N). \end{aligned}$$

First of all we observe that $u^j \in H_0^1(\hat{\Omega}; m_N)$ (see Proposition 4.1 below).

Let us consider the set $V = \text{Span}[u^1, u^2, \dots, u^k]$ which is a vector subspace of $H_0^1(\hat{\Omega}; m_N)$ with dimension k .

Let $v = \sum_{j=1}^k \alpha_j u^j \in V$ and $v_n = \sum_{j=1}^k \alpha_j u_n^j \in H_0^1(\Omega_n; m_N)$; then we have

$$\begin{aligned} v_n &\rightharpoonup v && \text{in } H^1(\mathbb{R}^N; m_N) \\ v_n &\rightarrow v && \text{in } L^2(\mathbb{R}^N; m_N). \end{aligned}$$

Thus

$$(4.4) \quad \frac{\int_{\mathbb{R}^N} |\nabla v|^2 dm_N}{\int_{\mathbb{R}^N} v^2 dm_N} \leq \liminf_n \frac{\int_{\mathbb{R}^N} |\nabla v_n|^2 dm_N}{\int_{\mathbb{R}^N} v_n^2 dm_N}$$

with

$$\int_{\mathbb{R}^N} v_n^2 dm_N = \sum_{j=1}^k \alpha_j^2; \quad \int_{\mathbb{R}^N} |\nabla v_n|^2 dm_N = \sum_{j=1}^k \alpha_j^2 \lambda_j(\Omega_n).$$

Being

$$\frac{\alpha_1^2}{\sum_{j=1}^k \alpha_j^2} \lambda_1(\Omega_n) + \dots + \frac{\alpha_k^2}{\sum_{j=1}^k \alpha_j^2} \lambda_k(\Omega_n) \leq \lambda_k(\Omega_n)$$

yields

$$\frac{\int_{\mathbb{R}^N} |\nabla v_n|^2 dm_N}{\int_{\mathbb{R}^N} v_n^2 dm_N} \leq \lambda_k(\Omega_n)$$

and then, for every $v \in V$, by (4.4) we get

$$\frac{\int_{\mathbb{R}^N} |\nabla v|^2 dm_N}{\int_{\mathbb{R}^N} v^2 dm_N} \leq \liminf_n \lambda_k(\Omega_n).$$

By the min-max formula (2.10) for $\lambda_k(\Omega)$ we have

$$\lambda_k(\hat{\Omega}) \leq \max_{v \in V} \frac{\int_{\mathbb{R}^N} |\nabla v|^2 dm_N}{\int_{\mathbb{R}^N} v^2 dm_N} \leq \liminf_n \lambda_k(\Omega_n),$$

which concludes the proof.

Proposition 4.1. *Let Ω_n be a minimizing sequence in problem (1.4) and let u_n^j be an eigenfunction associated to $\lambda_j(\Omega_n)$, $1 \leq j \leq k$, satisfying (4.3). For every $1 \leq j \leq k$ there exists $w^j \in H_0^1(\hat{\Omega}; m_N)$, with $\hat{\Omega}$ as in (4.2), such that*

$$(4.5) \quad u_n^j \rightharpoonup w^j \quad \text{in} \quad H^1(\mathbb{R}^N; m_N)$$

$$(4.6) \quad u_n^j \rightarrow w^j \quad \text{in} \quad L^2(\mathbb{R}^N; m_N).$$

Proof. We first observe that (4.5) and (4.6) are easy consequences of Theorem 2.2. It remains to prove that $w^j \in H_0^1(\hat{\Omega}; m_N)$. By (3.7) (see Remark 3.1) there exists a constant $M > 0$, whose value is independent from n , such that

$$\|u_n^j\|_\infty \leq M.$$

Suppose $\lambda_k(\Omega_n) \leq \Lambda$ for every n and, as in the proof of Theorem 1.1, let w_n be the solution to problem (4.1). The function $\psi_n^j = \Lambda M w_n - u_n^j$ satisfies

$$\begin{cases} -\Delta \psi_n^j - x \cdot \nabla \psi_n^j = f_n^j & \text{in } \Omega_n \\ \psi_n^j = 0 & \text{on } \partial\Omega_n \end{cases}$$

with $f_n^j = \Lambda M - \lambda_j(\Omega_n) u_n^j$ positive and bounded. By the maximum principle (see Proposition 4.2 below)

$$\psi_n^j \geq 0 \quad \text{in } \Omega_n,$$

that is

$$u_n^j \leq \Lambda M w_n.$$

Analogously we can prove that $-\Lambda M w_n \leq u_n^j$, and then

$$|u_n^j| \leq \Lambda M w_n.$$

Passing to the limit, we get

$$(4.7) \quad |w^j| \leq \Lambda M w \quad \text{a.e..}$$

Since $w = 0$ quasi-everywhere in $\mathbb{R}^N \setminus \hat{\Omega}$, (4.7) implies that $w^j \in H_0^1(\hat{\Omega}; m_N)$. □

Proposition 4.2. *Let D be an open set in \mathbb{R}^N with finite m_N -measure and let ψ be a solution to*

$$(4.8) \quad \begin{cases} -\Delta \psi - x \cdot \nabla \psi = f & \text{in } D \\ \psi = 0 & \text{on } \partial D \end{cases}$$

with $f \in L^\infty(D)$. If $f \geq 0$ in D then $\psi \geq 0$ in D .

Proof. Let $\eta = \psi e^{|x|^2/4}$. Clearly η satisfies

$$\begin{cases} -\Delta\eta + \left(\frac{|x|^2}{4} + \frac{N}{2}\right)\eta = f e^{-|x|^2/4} & \text{in } D \\ \eta = 0 & \text{on } \partial D. \end{cases}$$

Since $f \in L^\infty(D)$, by Talenti's theorem (see [27]) $\eta \in L^\infty(D)$. Let us consider the sequence of sets $D_k = D \cap B_k$, where B_k is the ball centered at the origin, with radius k ; it holds

$$D_1 \subset D_2 \subset \dots, \quad D \subseteq \cup_{k \in \mathbb{N}} D_k, \quad \partial D_k = \Gamma_k \cup \Gamma'_k \quad \text{with } \Gamma_k \subseteq \partial D, \Gamma'_k \subset D.$$

Let

$$\Phi_N(t) = \begin{cases} \ln |t| & \text{if } N = 2 \\ -|t|^{2-N} & \text{if } N \geq 3. \end{cases}$$

We distinguish two cases: (i) $0 \notin \bar{D}$, (ii) $0 \in \bar{D}$.

(i) Let $r_0 > 0$ be such that $|x| > r_0$ for every $x \in \bar{D}$. For any $k \in \mathbb{N}$ such that $k > r_0$ we define

$$w_k(x) = \begin{cases} \Phi_N(|x|) - \Phi_N(r_0), & x \in D_k \\ \Phi_N(k) - \Phi_N(r_0), & x \in D \setminus D_k \end{cases}$$

and

$$w(x) = \Phi_N(|x|) - \Phi_N(r_0), \quad x \in D.$$

By construction $w_k(x) \leq w(x)$ for every $x \in D$ and

$$\limsup_k \left(\inf_{\Gamma'_k} \frac{\eta}{w_k} \right) = \limsup_k \left(\frac{1}{\Phi_N(k) - \Phi_N(r_0)} \inf_{\Gamma'_k} \eta \right) = 0.$$

Moreover it satisfies

$$\begin{cases} -\Delta w_k + \left(\frac{|x|^2}{4} + \frac{N}{2}\right) w_k \geq 0 & \text{in } D_k \\ w_k > 0 & \text{on } D_k \cup \partial D_k. \end{cases}$$

By Theorem 19, p. 97 in [25] we get that $\eta \geq 0$ and hence $\psi \geq 0$ in D .

(ii) If $0 \notin \bar{D}$ it is enough to consider $\tilde{D}_k = D_k \setminus B_{2\varepsilon}(0)$ for $\varepsilon > 0$ and

$$\tilde{w}_k(x) = \begin{cases} \Phi_N(|x|) - \Phi_N(\varepsilon), & x \in \tilde{D}_k \\ \Phi_N(k) - \Phi_N(\varepsilon), & x \in D \setminus \tilde{D}_k. \end{cases}$$

Reasoning as in the case (i) we get that $\psi \geq 0$ in $D \setminus B_{2\varepsilon}(0)$ for every $\varepsilon > 0$ small enough. By continuity $\psi \geq 0$ in D . □

Remark 4.1. The previous maximum principle also holds for a quasi-open set D with finite m_N -measure. To see that, we proceed by external approximation D_ε , exactly as in Remark 3.1, and we use the fact that the (non-negative) solutions to problem (4.8) on D_ε converge to the solution of the same problem on D , thus this one is non negative.
